PRIMEIRA AVALIAÇÃO

Implementar Sistema Distribuído Cliente/Servidor que compartilham objetos em rede usando Java RMI ou Pyro

BELÉM 2020

Introdução

O objetivo deste trabalho é implementar um objeto servidor de perfis que possa ser acessado em máquinas ou redes diferentes por um cliente utilizando uma das duas tecnologias dedicadas a esta tarefa: Java RMI ou Pyro. Logo, teremos uma base de dados de perfil, acessível pelo cliente através de um objeto servidor compartilhado em rede.

Serão duas aplicações: a aplicação cliente e a aplicação servidor. A aplicação servidor irá armazenar os perfis e a aplicação cliente poderá consultar/inserir informações aos perfis somente acessando a aplicação servidora, sem acessar os perfis diretamente. Logo, a aplicação servidora protege o acesso direto aos perfis por parte do cliente e define o que e como o cliente pode acessar em relação aos perfis.

Cliente e servidor executarão em redes diferentes, logo, o objeto servidor deve ser disponibilizado ao cliente remotamente para que assim o cliente consiga ter acesso aos perfis.

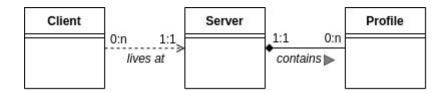

Figura 01: Esboço geral da aplicação.

Como vemos na figura 01, um cliente (aplicação cliente, e não um objeto) acessa um e somente um objeto servidor, e um objeto servidor pode estar sendo acessado por nenhum ou muitos clientes. Logo, a relação entre cliente e servidor é de dependência, pois o cliente depende do servidor.

Da figura 01, também temos que um objeto servidor contém 0 ou muitos objetos de perfis e que todo objeto de perfil deve estar contido em um e somente um objeto servidor. Essa é uma relação de associação/composisção, onde a classe que possui o dimante negro (*Server*) controla a associação e, além disso, a outra classe (*Profile*) não pode estar associada a outras instâncias.

Metodologia

Para realizar este trabalho, será utilizada a linguagem python 3.8 e as seguintes bibliotecas: *Pyro* versão 4.80, *typing* versão 3.7.4.3, *matplotlib* versão 3.3.3 e *PyQt5* versão 5.15.2.

<u>Pyro</u> foi utilizada para disponibilizar o acesso remoto ao objeto servidor de perfis, <u>typing</u> foi utilizada para criar anotações de tipos de variáveis e retorno de métodos que ajudam o programador a entender o código com muito mais clareza e facilidade, <u>matplotlib</u> para criar gráficos e <u>PyQt5</u> para renderizar os gráficos na tela.

Considerando que não foi especificado qual banco de dados que deve ser usado, tampouco se o mesmo deve ser relacional ou não-relacional, foi criada uma classe chamada *Profile*, que será utilizada, pelo servidor, para criar objetos de perfis. O servidor armazenará esses objetos em uma lista.

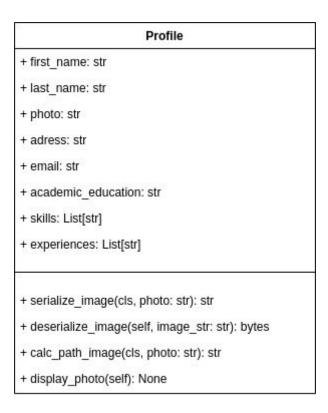

Figura 02: Diagrama UML da classe *Profile*.

Todos os atributos de *Profile* são públicos. A classe *Profile* possui um método construtor que requer cada um dos atributos listados. Importante ressaltar que como os objetos perfis são possuem uma imagem/foto, logo, foram adicionados métodos para serializar e deserializar a imagem.

No método construtor da classe *Profile*, o nome da foto é recebido em string, e passado para a função *serialize_image*, que então invoca o método *calc_path_image*, que por sua vez retorna para a função que o invocou o caminho absoluto para a imagem, onde então a imagem é aberta em sua forma binária, codifica para base 64 e convertida para string, onde então essa string referente codificação em base 64 é armazenada no atributo *photo* da instância da *Profile*. Isso permite que a imagem trafegue em forma de string na rede.

A aplicação cliente irá utilizar o método *display_photo* para exibir a imagem no lado do cliente. Este método invoca o método deserialize para transformar a imagem de volta para bytes e exibir na tela.

O objeto servidor de perfis é definido no diagrama abaixo.

+ hello(msg: str): str + list_profiles_of_a_course(course: str): Dict + list_skills_of_profiles_of_a_city(address: str): list + put_new_experience_in_a_profile(email: str, experience: str): None + list_experiences_from_email_profile(email: str): Union[List[str], None] + list_all_informations_of_all_profiles(): Dict + list_all_informations_of_profile_by_its_email(email: str): Dict + display_photo(cls, email: str) -> None

Figura 03: Diagrama UML da classe Server.

Todos os métodos da classe *Server* são públicos e estáticos. O método construtor da classe *Server* é vazio. Cada método é auto explicativo e especifica os tipos de argumentos e o tipo de retorno.

É importante ressaltar que a instância de *Server* não retorna para a aplicação cliente os objetos em si (pois somente a instância de *Server* está disponível remotamente), e sim as informações contidas na lista de instâncias de *Profile* em forma de dicionário ou lista de dicionários, pois dessa forma, a base de dados em memória (que é a lista de instâncias de *Profile*) se mantém seguras.

- O método <u>hello</u> é apenas para teste, para saber se a aplicação cliente conseguiu acessar a instância de *Server*, onde a aplicação cliente envia uma string que vai ser exibida no console da aplicação servidora;
- O método <u>display_photo</u> é uma wrapper para o método <u>display_photo</u> da instância de Profile que se deseja exibir a foto;
- Os demais métodos são auto explicativos e internamente.

As fotos dos perfis foram armazenadas na pasta *photos*. A aplicação servidora, por efeitos de estudo, e não de cenário real, poderá instanciar 3 perfis. Segue abaixo a foto dos 3 perfis.

Figura 04: Foto do perfil do Bruno.

Figura 05: Foto do perfil do Renato.

Figura 05: Foto do perfil do Cassio.

Após as classes definidas, foi dado início a construção das aplicações cliente e servidor que foram criadas, respectivamente nos arquivos app client.py e app server.py.

Aplicação Servidor

app_server.py

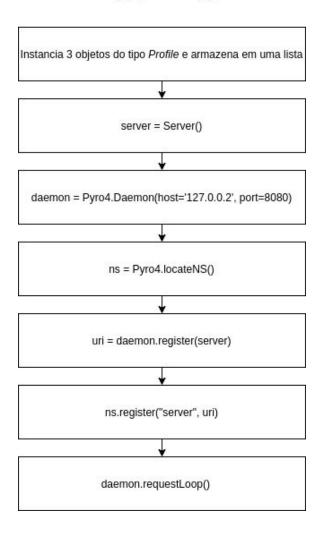

Figura 06: aplicação servidora (app_server.py)

Da figura 06:

- Inicialmente, foi instanciado os perfis de Bruno, Renato e Cassio e armazenado em uma lista, que atuará como a base de dados em memória de perfis;
- Foi instanciado o objeto servidor de perfis;
- $\underline{ns} = Pyro4.locateNS()$: aloca-se o nameserver;
- <u>daemon = Pyro4.Daemon(host='127.0.0.2', port=8080)</u>: cria um deamon Pyro para ouvir chamadas remotas, onde vale ressaltar que todo objeto Pyro é registrado em um ou mais deamons
- uri = daemon.register(server): registra o objeto servidor de perfis como um objeto
 Pyro, onde uri (unique resource locator) é o identificador do objeto servidor de perfis na rede;
- <u>ns.register("server", uri)</u>: o objeto servidor de perfis é registrado com um nome no servidor de nomes (nameserver)

```
decorators.py x app_server.py x requirements.txt x
db li profiles: List[Profile] = []
p1 = Profile(first name='Bruno', last name='Conde Costa da Silva', \
    photo='bruno.png', address='Ananindeua', email='bruno@email.com', \
    academic education='Engenharia da Computação', skills=['Python'], \
    experiences=['Ciencia de dados', 'Desenvolvimento Web'])
p2 = Profile(first name='Renato', last name='Sousa da Silva', \
    photo='renato.png', address='Ananindeua', email='renato@email.com', \
    academic education='Engenharia da Computação', skills=['Cobol'], \
    experiences=['infra'])
p3 = Profile(first name='Cassio', last name='Sousa da Silva', \
    photo='cassio.png', address='Bragança', email='cassio@email.com', \
    academic education='Educação Física', skills=['Cobol'], \
    experiences=['xadrez na praça'])
db li profiles.append(p1)
db li profiles.append(p2)
db li profiles.append(p3)
```

Figura 07: Instanciando os 3 perfis mencionados acima.

Após a criação da base de dados em memória de perfis, foi configurado um *nameserver* no endereço 127.0.0.1, em uma porta arbitrária definida pelo pacote Pyro4, que vai servir o objeto server, que é uma instância da classe Server, que irá prover informações sobre os objetos perfis (instâncias da classe *Profile*). Fazemos isso ao executar o comando **python -m Pyro4.naming**

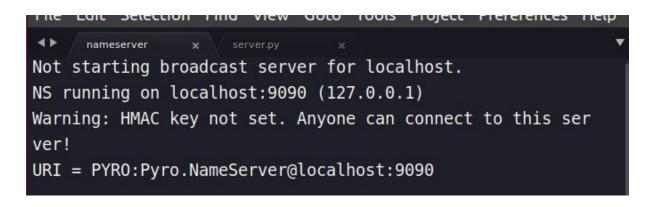

Figura 08: nameserver.

Após inicializar o *nameserver*, é inicializado no endereço 127.0.0.2, porta 8080, o daemon, que fica , em rodando, em background, um loop multi thread para receber requisições do cliente, via Proxy, para o objeto remoto, no endereço 127.0.0.1, porta randômica, hospedado pelo nameserver, via intermédio do servidor de daemon.

Figura 09: daemon.

app_client.py

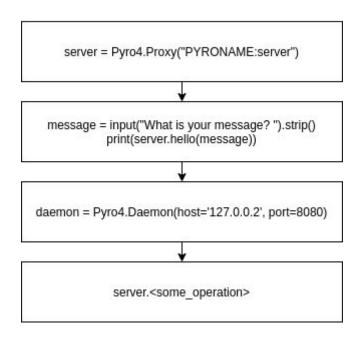

Figura 10: aplicação cliente (app client.py)

Na figura 10, temos a aplicação cliente:

- server = Pyro4.Proxy("PYRONAME:server"): cliente acessa a instância de Server de forma remota via Proxy, passando o uri server, que foi o uri atribuído ao objeto server e registrado no nameserver. Agora o cliente pode acessar qualquer método remoto da instância de Server como se fosse um objeto local.
- Após isso, o cliente envia uma mensagem para o servidor, que vai ser exibida no console do servidor. Isto só serve para saber que o cliente está acessando corretamente o servidor remoto.
- Após isso, basta o cliente executar qualquer método utilizando o objeto server local, que na verdade é um acesso via proxy para o objeto remoto que realmente está instanciado.

Para fazer a contagem do tempo de cada operação e plotar os gráficos foram criadas, respectivamente, as funções <u>calc_time</u> e <u>calc_plot</u>. Elas são funções decoradoras, que atuam como wrapper para as operações que queremos calcular o tempo e plotar o gráfico. Funciona da seguinte forma: antes de cada operação/método da classe <u>Server</u>, é colocado um decorator <u>@calc_plot</u> e <u>@calc_time</u>. <u>@calc_time</u> atua como wrapper para operação/método em si, e toda vez que a operação precedida por <u>@calc_time</u> é invocada, <u>calc_time</u> executa a

operação/método em seu escopo interno e, antes de executar, registra o tempo antes e depois do final de execução da operação e assim calcula o tempo de execução da operação bem como obtém também o resultado da operação/método em si. *calc_time* passa para a função *calc_plot* a lista de tempo de execuções que a operação levou em cada execução e o resultado da operação/método em si, e então, *calc_plot* faz o gráfico e salva ou plota, dependendo se a variável *DEBUG* do módulo *decorators.py* (que contém as duas funções decoradoras) estivar setada como True ou False.

Ainda em <u>decorators.py</u>, a variável <u>N_PLOTS</u> e <u>CONFIDENCE</u> recebem, respectivamente, o número de vezes que é pra executar o método e o valor de confiança para o cálculo estatístico.

Resultados

Quadro 01: retorno de server.list profiles of a course(course='Engenharia da Computação').

Logo, cada operação foi implementada com sucesso. É importante ressaltar que não foram adicionados todos os tratamentos de erro necessários para que, por exemplo, não insira uma habilidade que já esteja registrada. Esses detalhes de implementação são importantes em um cenário real, mas para fins acadêmicos, somente a funcionalidade chave deste trabalho foi devidamente desenvolvida: realizar chamada remota de objetos em máquinas/redes diferentes.

Além do mais, em um cenário real, não se utilizaria uma lista de objetos como base de dados e sim uma base de dados relacional ou não relacional, como por exemplo, MySQL e MongoDB, respectivamente.

Para efeito de avaliação de desempenho, foi definido N_PLOTS=20, executando 20 vezes cada operação e calculando o tempo em cada uma delas, plotando o gráfico. Também foi considerado a confiança, na variável *CONFIDENDE* no módulo *decorators.py*, como sendo igual a 0.95. Tome *delta*, nos gráficos abaixo, como sendo a variância. A variância quer dizer o quão distante da média os pontos estão.

Logo, como a variância é baixa em todas as operações, então, os tempos de execução se encontram próximos da média, havendo apenas alguns pontos distantes, como por exemplo, o tempo da primeira execução, que precisa carregar para memória variáveis e outras coisas necessárias para a execução do programa.

Este ponto da primeira execução (*warmup*) é considerado um outlier e, se fôssemos plotar um boxplot, veríamos nitidamente que ele se encontraria bem distante dos demais.

O nível de confiança de 0.95 estabelece que podemos esperar, com taxa de acerto de 95 % dos casos, que o tempo de execução vai se encontrar na média entre "*m - delta*" e "*m + delta*". O intervalo de confiança, então é definido como *P(m - delta < m < m + delta)=0.95*, que em síntese diz que há 95 % de chance de uma execução se encontrar entre "*m - delta*" e "*m + delta*".

Devemos considerar também que não foi feito um controle exato sobre os processos em execução no sistema operacional no instante em que foi calculado o tempo de execução de cada operação. Logo, o cálculo de tempo certamente foi interferido por outros processos que ocupam processador e a memória que não possuíam controle no momento da aferição.

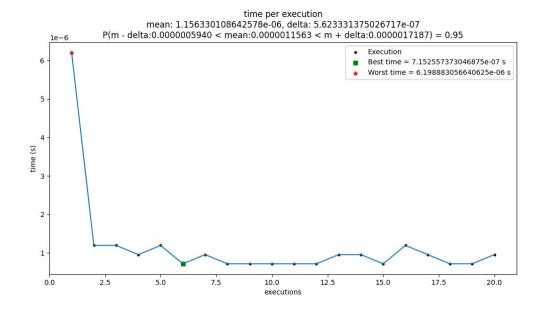

Figura 11: server.list_profiles_of_a_course(course='Engenharia da Computação')

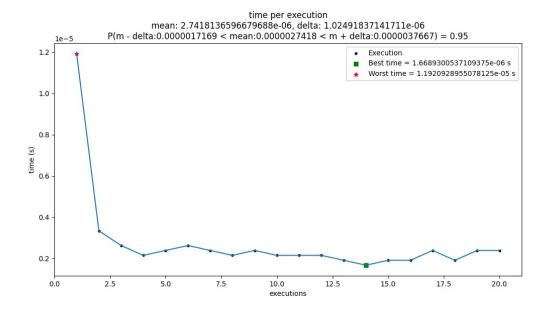

Figura 12: server.list_skills_of_profiles_of_a_city(address="Ananindeua")

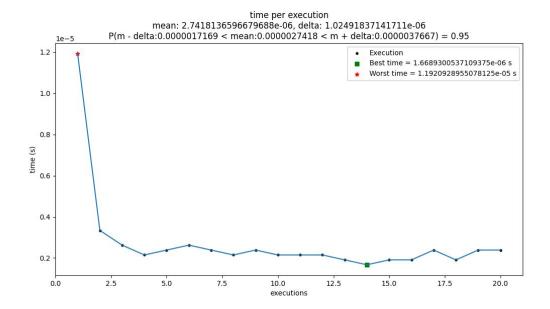

Figura 13: server.list_experiences_from_email_profile(email='bruno@email.com')

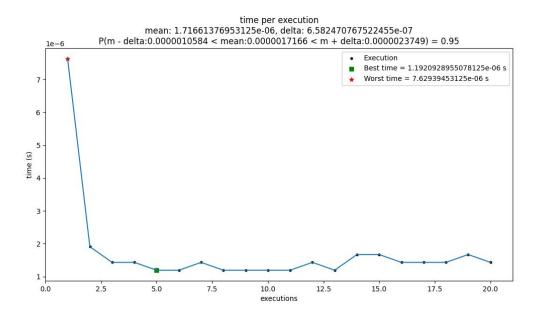

Figura 14: server.list_experiences_from_email_profile(email='cassio@email.com')

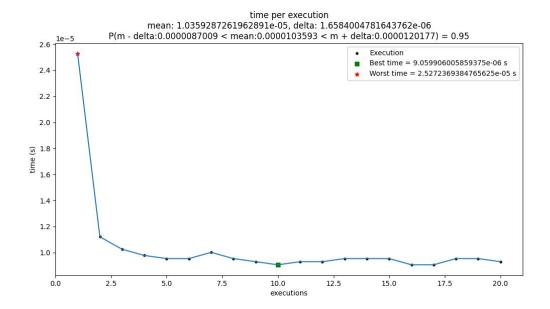

Figura 15: server.list all informations of all profiles()

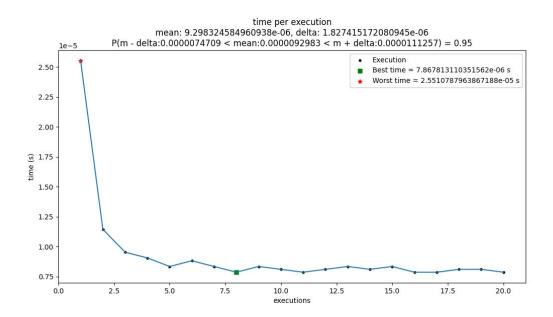

Figura 16: server.list all informations of profile by its email(email="renato@email.com")

Como podemos ver, a aplicação apresenta bom desempenho e tempo médio de execução baixo. A operação que é a **mais computacional custosa** é a operação **server.list_all_informations_of_all_profiles()** se considerarmos seu **tempo médio** de execução igual a **1.035x10**-5. Isso faz sentido pois ela acessa todas as informações de todos os perfis.

É importante ressaltar que o tempo de execução da operação ocorre no lado do servidor, e não leva em conta o tempo de comunicação entre cliente e servidor, pois os decoradores foram postos precedendo cada operação na definição da classe servidor, então quando o início da contagem do tempo é feito, o objeto servidor já foi acessado pelo cliente e, quando o cálculo da contagem do término da execução é feito, é registrado o tempo em que a operação finaliza ainda do lado servidor.

Infelizmente, não foi possível corrigir isso a tempo, mas uma solução é, no lado cliente, o cliente registra o tempo antes e depois de realizar a operação. Assim é possível aferir o tempo de execução da operação levando em conta o tempo de comunicação entre cliente e servidor.
